Data Science for Economists

Lecture 11: Data cleaning & wrangling: Tidyverse

Alex Marsh University of North Carolina | ECON 390

Table of contents

- 1. Prologue
- 2. Tidyverse basics
- 3. Data wrangling with dplyr
 - filter
 - arrange
 - select
 - mutate
 - summarize
 - joins
- 4. Data tidying with tidyr
 - pivot_longer / pivot_wider
 - separate and unite
- 5. Summary
- * Slides adapted from Grant McDermott's EC 607 at University of Oregon.

Prologue

What is "tidy" data?

Resources:

- Vignette (from the **tidyr** package)
- Original paper (Hadley Wickham, 2014 JSS)

What is "tidy" data?

Resources:

- Vignette (from the **tidyr** package)
- Original paper (Hadley Wickham, 2014 JSS)

Key points:

- 1. Fach variable forms a column.
- 2. Each observation forms a row.
- 3. Each type of observational unit forms a table.

What is "tidy" data?

Resources:

- Vignette (from the **tidyr** package)
- Original paper (Hadley Wickham, 2014 JSS)

Key points:

- 1. Fach variable forms a column.
- 2. Each observation forms a row.
- 3. Each type of observational unit forms a table.

Basically, tidy data is more likely to be long (i.e. narrow) format than wide format.

Checklist

R packages you'll need today

- **☑ tidyverse**
- **☑** nycflights13

Checklist

R packages you'll need today

- **☑ tidyverse**
- **☑** nycflights13

I'll hold off loading these libraries for now. But you can install/update them both with the following command.

```
install.packages(c('tidyverse', 'nycflights13'), repos = 'https://cran.rstudio.com',
```

Tip: If you're on Linux, then I *strongly* recommend installing the pre-compiled binary versions of these packages from RSPM instead of CRAN. The exact repo mirror varies by distro (see the link). But on Ubuntu 20.04, for example, you'd use:

```
install.packages(c('tidyverse', 'nycflights13'), repos = 'https://packagemanager.rstuc
```

Tidyverse basics

Tidyverse vs. base R

Much digital ink has been spilled over the "tidyverse vs. base R" debate.

Tidyverse vs. base R

Much digital ink has been spilled over the "tidyverse vs. base R" debate.

I won't delve into this debate here, because I think the answer is clear: We should teach the tidyverse first (or, at least, early).

- The documentation and community support are outstanding.
- Having a consistent philosophy and syntax makes it easier to learn.
- Provides a convenient "front-end" to big data tools that we'll use later in the course.
- For data cleaning, wrangling, and plotting, the tidyverse really is a no-brainer.¹

¹ As y'all know, I'm also a huge fan of **data.table**.

Tidyverse vs. base R

Much digital ink has been spilled over the "tidyverse vs. base R" debate.

I won't delve into this debate here, because I think the answer is clear: We should teach the tidyverse first (or, at least, early).

- The documentation and community support are outstanding.
- Having a consistent philosophy and syntax makes it easier to learn.
- Provides a convenient "front-end" to big data tools that we'll use later in the course.
- For data cleaning, wrangling, and plotting, the tidyverse really is a no-brainer.¹

But... this certainly shouldn't put you off learning base R alternatives.

- Base R is extremely flexible and powerful (and stable).
- There are some things that you'll have to venture outside of the tidyverse for.
- A combination of tidyverse and base R is often the best solution to a problem.
- Excellent base R data manipulation tutorials: here and here.

¹ As y'all know, I'm also a huge fan of **data.table**.

Tidyverse vs. base R (cont.)

One point of convenience is that there is often a direct correspondence between a tidyverse command and its base R equivalent.

These generally follow a tidyverse::snake_case vs base::period.case rule. E.g. Compare:

tidyverse	base
?readr::read_csv	<pre>?utils::read.csv</pre>
?dplyr::if_else	?base::ifelse
<pre>?tibble::tibble</pre>	?base::data.frame

Etcetera.

If you call up the above examples, you'll see that the tidyverse alternative typically offers some enhancements or other useful options (and sometimes restrictions) over its base counterpart.

Tidyverse vs. base R (cont.)

One point of convenience is that there is often a direct correspondence between a tidyverse command and its base R equivalent.

These generally follow a tidyverse::snake_case vs base::period.case rule. E.g. Compare:

tidyverse	base
?readr::read_csv	<pre>?utils::read.csv</pre>
?dplyr::if_else	?base::ifelse
<pre>?tibble::tibble</pre>	?base::data.frame

Etcetera.

If you call up the above examples, you'll see that the tidyverse alternative typically offers some enhancements or other useful options (and sometimes restrictions) over its base counterpart.

Remember: There are (almost) always multiple ways to achieve a single goal in R.

Tidyverse packages

Let's load the tidyverse meta-package and check the output.

Tidyverse packages

Let's load the tidyverse meta-package and check the output.

We see that we have actually loaded a number of packages (which could also be loaded individually): **ggplot2**, **tibble**, **dplyr**, etc.

 We can also see information about the package versions and some namespace conflicts.

Tidyverse packages (cont.)

The tidyverse actually comes with a lot more packages than those that are just loaded automatically.¹

```
tidvverse packages()
                        "cli"
                                        "cravon"
                                                        "dbplvr"
   [1] "broom"
                                        "forcats"
                                                        "googledrive"
   [5] "dplyr"
                        "dtplyr"
   [9] "googlesheets4" "ggplot2"
                                        "haven"
                                                        "hms"
                                        "lubridate"
                                                        "magrittr"
  [13] "httr"
                  "isonlite"
                       "pillar"
                                        "purrr"
                                                        "readr"
  [17] "modelr"
  [21] "readxl"
                       "reprex"
                                        "rlang"
                                                        "rstudioapi"
                       "stringr"
                                        "tibble"
                                                        "tidvr"
## [25] "rvest"
                        "tidvverse"
## [29] "xml2"
```

- E.g. The **lubridate** package for working with dates and the **rvest** package for webscraping.
- However, bear in mind that these packages will have to be loaded separately.

¹ It also includes a *lot* of dependencies upon installation. This is a matter of some controversy.

Tidyverse packages (cont.)

I hope to cover most of the tidyverse packages over the length of this course.

Today, however, I'm only really going to focus on two packages:

- 1. dplyr
- 2. tidyr

These are the workhorse packages for cleaning and wrangling data. They are thus the ones that you will likely make the most use of (alongside **ggplot2**, which we already met back in Lecture 1).

• Data cleaning and wrangling occupies an inordinate amount of time, no matter where you are in your research career.

An aside on pipes: %>%

The tidyverse uses a pipe %>% which lets you send (i.e. "pipe") intermediate output to another command.

In other words, it allows us to chain together a sequence of simple operations and thereby implement a more complex operation.

I want to reiterate how cool pipes are, and how using them can dramatically improve the experience of reading and writing code. Compare:

```
## These next two lines of code do exactly the same thing.
mpg %>% filter(manufacturer="audi") %>% group_by(model) %>% summarize(hwy_mean = mear
summarize(group_by(filter(mpg, manufacturer="audi"), model), hwy_mean = mean(hwy))
```

An aside on pipes: %>%

The tidyverse uses a pipe %>% which lets you send (i.e. "pipe") intermediate output to another command.

In other words, it allows us to chain together a sequence of simple operations and thereby implement a more complex operation.

I want to reiterate how cool pipes are, and how using them can dramatically improve the experience of reading and writing code. Compare:

```
## These next two lines of code do exactly the same thing.
mpg %>% filter(manufacturer="audi") %>% group_by(model) %>% summarize(hwy_mean = mean
summarize(group_by(filter(mpg, manufacturer="audi"), model), hwy_mean = mean(hwy))
```

The first line reads from left to right, exactly how I thought of the operations in my head.

• Take this object (mpg), do this (filter), then do this (group_by), etc.

The second line totally inverts this logical order (the final operation comes first!)

• Who wants to read things inside out?

An aside on pipes: %>% (cont.)

The piped version of the code is even more readable if we write it over several lines. Here it is again and, this time, I'll run it for good measure so you can see the output:

```
mpg %>%
  filter(manufacturer="audi") %>%
  group by(model) %>%
  summarize(hwy mean = mean(hwy))
## # A tibble: 3 x 2
###
    model
              hwy mean
    <chr> <dbl>
###
          28.3
## 1 a4
              25.8
## 2 a4 quattro
## 3 a6 quattro
              24
```

Remember: Using vertical space costs nothing and makes for much more readable/writeable code than cramming things horizontally.

An aside on pipes: %>% (cont.)

The piped version of the code is even more readable if we write it over several lines. Here it is again and, this time, I'll run it for good measure so you can see the output:

```
mpg %>%
  filter(manufacturer="audi") %>%
  group by(model) %>%
  summarize(hwy mean = mean(hwy))
## # A tibble: 3 x 2
###
    model
              hwy mean
    <chr> <dbl>
###
          28.3
## 1 a4
              25.8
## 2 a4 quattro
## 3 a6 quattro
              24
```

Remember: Using vertical space costs nothing and makes for much more readable/writeable code than cramming things horizontally.

PS — The pipe is originally from the **magrittr** package, which can do some other cool things if you're inclined to explore.

dplyr

Aside: dplyr 1.0.0 release

Some of the **dplyr** features that we'll cover today were introduced in version 1.0.0 of the package.

- Version 1.0.0 is a big deal since it marks a stable code base for the package going forward. However, at the time of writing these slides, it had only come out very recently.
- Please make sure that you are running at least **dplyr** 1.0.0 before continuing.

```
packageVersion('dplyr')
## [1] '1.0.7'
# install.packages('dplyr') ## install updated version if < 1.0.0</pre>
```

Aside: dplyr 1.0.0 release

Some of the **dplyr** features that we'll cover today were introduced in version 1.0.0 of the package.

- Version 1.0.0 is a big deal since it marks a stable code base for the package going forward. However, at the time of writing these slides, it had only come out very recently.
- Please make sure that you are running at least **dplyr** 1.0.0 before continuing.

```
packageVersion('dplyr')
## [1] '1.0.7'
# install.packages('dplyr') ## install updated version if < 1.0.0</pre>
```

Note: **dplyr** 1.0.0 also notifies you about grouping variables every time you do operations on or with them. YMMV, but, personally, I find these messages annoying and so prefer to switch them off.

```
options(dplyr.summarize.inform = FALSE) ## Add to .Rprofile to make permanent
```

Key dplyr verbs

There are five key dplyr verbs that you need to learn.

- 1. filter: Filter (i.e. subset) rows based on their values.
- 2. arrange: Arrange (i.e. reorder) rows based on their values.
- 3. select: Select (i.e. subset) columns by their names:
- 4. mutate: Create new columns.
- 5. summarize: Collapse multiple rows into a single summary value. 1

¹ summarise with a "s" works too.

Key dplyr verbs

There are five key dplyr verbs that you need to learn.

- 1. filter: Filter (i.e. subset) rows based on their values.
- 2. arrange: Arrange (i.e. reorder) rows based on their values.
- 3. select: Select (i.e. subset) columns by their names:
- 4. mutate: Create new columns.
- 5. summarize: Collapse multiple rows into a single summary value. 1

Let's practice these commands together using the starwars data frame that comes prepackaged with dplyr.

¹ summarise with a "s" works too.

1) dplyr::filter

We can chain multiple filter commands with the pipe (%>%), or just separate them within a single filter command using commas.

```
starwars %>%
  filter(
    species = "Human",
    height ≥ 190
## # A tibble: 4 x 14
              height mass hair color skin color eye color birth year sex
                                                                           gender
##
    name
          <int> <dbl> <chr>
    <chr>
                                      <chr>
                                                <chr>
                                                               <dbl> <chr> <chr>
###
                                     white

```

Note: Arranging on a character-based column (i.e. strings) will sort alphabetically. Try this yourself by arranging according to the "name" column.

2) dplyr::arrange cont.

We can also arrange items in descending order using arrange(desc()).

```
starwars %>%
   arrange(desc(birth vear))
## # A tibble: 87 x 14
##

```

3) dplyr::select

Use commas to select multiple columns out of a data frame. (You can also use "first:last" for consecutive columns). Deselect a column with "-".

```
starwars %>%
  select(name:skin color, species, -height)
## # A tibble: 87 x 5
                         mass hair color
                                           skin color
                                                       species
##
     name

## # ... with 77 more rows
```

If you just want to rename columns without subsetting them, you can use rename. Try this now by replacing select(...) in the above code chunk with rename(...).

The select(contains(PATTERN)) option provides a nice shortcut in relevant cases.

```
starwars %>%
  select(name, contains("color"))
## # A tibble: 87 x 4
                      hair color
                                   skin color eye color
##
     name
###
   <chr>
                      <chr>
                                   <chr>
                                              <chr>
                      blond
                                   fair blue
###
  1 Luke Skywalker
                                   gold yellow
   2 C-3P0
                      <NA>

```

The select(..., everything()) option is another useful shortcut if you only want to bring some variable(s) to the "front" of a data frame.

```
starwars %>%
  select(species, homeworld, everything()) %>%
  head(5)
## # A tibble: 5 x 14
###
   species homeworld name
                                 height mass hair color skin color
                                                                eye color
    <chr> <chr> <chr>
                                  <int> <dbl> <chr>
                                                     <chr>
                                                                 <chr>>
###
                                                      fair
                                                                blue

                                                            <chr>
                                                  fair
## 1 Human Tatooine Luke Skywalker 172 77 blond
                                                            blue
                          167 75 <NA>
                                                  gold yellow
## 2 Droid Tatooine C-3PO
## 3 Droid Naboo R2-D2
                                                  white, blue red
                         96 32 <NA>
## 4 Human Tatooine Darth Vader 202 136 none
                                                  white yellow
## 5 Human Alderaan Leia Organa 150 49 brown
                                                  light
                                                            brown
## # ... with 6 more variables: birth year <dbl>, sex <chr>, gender <chr>,
## # films <list>, vehicles <list>, starships <list>
```

Note: The new relocate function available in dplyr 1.0.0 has brought a lot more functionality to ordering of columns. See here.

4) dplyr::mutate

You can create new columns from scratch, or (more commonly) as transformations of existing columns.

```
starwars %>%
  select(name, birth year) %>%
  mutate(dog years = birth year * 7) %>%
  mutate(comment = paste0(name, " is ", dog_years, " in dog years."))
## # A tibble: 87 x 4
##
     name
                         birth year dog years comment
   <chr>
                              < [db] >
                                        <dbl> <chr>
###

## 10 Obi-Wan Kenobi
                                              Obi-Wan Kenobi is 399 in dog years.
                               57
                                         399
## # ... with 77 more rows
                                                                                     27 / 54
```

Boolean, logical and conditional operators all work well with mutate too.

150

5 LEIA ORGANA

Lastly, combining mutate with the new across feature in dplyr 1.0.0+ allows you to easily work on a subset of variables. For example:

```
starwars %>%
  select(name:eye color) %>%
  mutate(across(where(is.character), toupper)) %>%
  head(5)
## # A tibble: 5 x 6
                   height mass hair color skin color
##
    name
                                                       eye color
                   <int> <dbl> <chr>
                                           <chr>
                                                       <chr>>
##
    <chr>
## 1 LUKE SKYWALKER
                      172
                          77 BLOND
                                           FAIR
                                                      BLUE
## 2 C-3P0
                      167 75 <NA>
                                           GOLD
                                                      YELLOW
## 3 R2-D2
                      96 32 <NA>
                                           WHITE, BLUE RED
## 4 DARTH VADER
                      202
                            136 NONE
                                           WHITE
                                                      YELLOW
```

##
## 1 LUKE SKYWALKER 172
                         77 BLOND
                                         FAIR
                                                    BLUE
## 2 C-3PO
                     167 75 <NA>
                                         GOLD
                                                    YELLOW
## 3 R2-D2
                     96 32 <NA>
                                         WHITE, BLUE RED
## 4 DARTH VADER
                     202
                           136 NONE
                                         WHITE
                                                    YELLOW
## 5 LEIA ORGANA
                     150
                            49 BROWN
                                         LIGHT
                                                    BROWN
```

Note: This workflow (i.e. combining mutate and across) supersedes the old "scoped" variants of mutate that you might have used previously. More details here and here.

5) dplyr::summarize

Particularly useful in combination with the group_by command.

```
starwars %>%
  group by(species, gender) %>%
  summarize(mean height = mean(height, na.rm = TRUE))
## summarise() has grouped output by 'species'. You can override using the .groups argumen
## # A tibble: 42 x 3
## # Groups: species [38]
   species gender mean height
##
   <chr> <chr>
                              <dbl>

###
## 10 Geonosian masculine
                                183
## # ... with 32 more rows
                                                                              30 / 54
```

5) dplyr::summarize cont.

Note that including "na.rm = TRUE" (or, its alias "na.rm = T") is usually a good idea with summarize functions. Otherwise, any missing value will propagate to the summarized value too.

```
## Probably not what we want
starwars %>%
   summarize(mean height = mean(height))
## # A tibble: 1 x 1
    mean height
##
           <dbl>
###
## 1
              NA
## Much hetter
starwars %>%
   summarize(mean height = mean(height, na.rm = TRUE))
## # A tibble: 1 x 1
###
    mean height
           <dbl>
###
         174.
## 1
```

5) dplyr::summarize cont.

The same across -based workflow that we saw with mutate a few slides back also works with summarize. For example:

```
starwars %>%
  group by(species) %>%
  summarize(across(where(is.numeric), mean, na.rm=T)) %>%
  head(5)
## # A tibble: 5 x 4
    species height mass birth year
##
                               <dbl>
    <chr> <dbl> <dbl>
###
## 1 Aleena 79
                       15
                                 NaN
## 2 Besalisk
                198
                      102
                                 NaN
## 3 Cerean
                198
                    82
                                 92
## 4 Chagrian
             196
                      NaN
                                 NaN
  5 Clawdite
                168
                       55
                                 NaN
```

5) dplyr::summarize cont.

The same across -based workflow that we saw with mutate a few slides back also works with summarize. For example:

```
starwars %>%
  group by(species) %>%
  summarize(across(where(is.numeric), mean, na.rm=T)) %>%
  head(5)
## # A tibble: 5 x 4
    species height mass birth year
##
    <chr> <dbl> <dbl>
                              <dbl>
###
## 1 Aleena 79
                                NaN
                      15
## 2 Besalisk
               198
                     102
                                NaN
## 3 Cerean
           198
                    82
                                92
## 4 Chagrian 196
                     NaN
                                NaN
## 5 Clawdite
                168
                      55
                                NaN
```

Note: Again, this functionality supersedes the old "scoped" variants of summarize that you used prior to dplyr 1.0.0. Details here and here.

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarize and mutate commands, as we've already seen.

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarize and mutate commands, as we've already seen.

slice: Subset rows by position rather than filtering by values.

• E.g. starwars %>% slice(c(1, 5))

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarize and mutate commands, as we've already seen.

slice: Subset rows by position rather than filtering by values.

• E.g. starwars %>% slice(c(1, 5))

pull: Extract a column from as a data frame as a vector or scalar.

• E.g. starwars %>% filter(gender="female") %>% pull(height)

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarize and mutate commands, as we've already seen.

slice: Subset rows by position rather than filtering by values.

• E.g. starwars %>% slice(c(1, 5))

pull: Extract a column from as a data frame as a vector or scalar.

• E.g. starwars %>% filter(gender="female") %>% pull(height)

count and distinct: Number and isolate unique observations.

- E.g. starwars %>% count(species), Or starwars %>% distinct(species)
- You could also use a combination of mutate, group_by, and n(), e.g. starwars %>% group_by(species) %>% mutate(num = n()).

Other dplyr goodies (cont.)

There are also a whole class of window functions for getting leads and lags, ranking, creating cumulative aggregates, etc.

• See vignette("window-functions").

Other dplyr goodies (cont.)

There are also a whole class of window functions for getting leads and lags, ranking, creating cumulative aggregates, etc.

• See vignette("window-functions").

The final set of dplyr "goodies" are the family of join operations. However, these are important enough that I want to go over some concepts in a bit more depth...

• We will encounter and practice these many more times as the course progresses.

Joins

One of the mainstays of the dplyr package is merging data with the family join operations.

```
• inner_join(df1, df2)
```

- left_join(df1, df2)
- right_join(df1, df2)
- full_join(df1, df2)
- semi_join(df1, df2)
- anti_join(df1, df2)

(You find find it helpful to to see visual depictions of the different join operations here.)

Joins

One of the mainstays of the dplyr package is merging data with the family join operations.

```
inner_join(df1, df2)left_join(df1, df2)right_join(df1, df2)full_join(df1, df2)
```

- semi_join(df1, df2)
- anti_join(df1, df2)

(You find find it helpful to to see visual depictions of the different join operations here.)

For the simple examples that I'm going to show here, we'll need some data sets that come bundled with the **nycflights13** package.

• Load it now and then inspect these data frames in your own console.

```
library(nycflights13)
flights
planes
```

Let's perform a left join on the flights and planes datasets.

• Note: I'm going subset columns after the join, but only to keep text on the slide.

Let's perform a left join on the flights and planes datasets.

• Note: I'm going subset columns after the join, but only to keep text on the slide.

```
left join(flights, planes) %>%
   select(year, month, day, dep time, arr time, carrier, flight, tailnum, type, model)
## Joining, by = c("year", "tailnum")
## # A tibble: 336.776 x 10
       vear month
                    day dep time arr time carrier flight tailnum type
                                                                         model
##

   10
       2013
                1
                       1
                              558
                                       753 AA
                                                       301 N3ALAA
                                                                   <NA>
                                                                         <NA>
   # ... with 336,766 more rows
                                                                                     36 / 54
```

(continued from previous slide)

Note that dplyr made a reasonable guess about which columns to join on (i.e. columns that share the same name). It also told us its choices:

```
## Joining, by = c("year", "tailnum")
```

However, there's an obvious problem here: the variable "year" does not have a consistent meaning across our joining datasets!

• In one it refers to the *year of flight*, in the other it refers to *year of construction*.

(continued from previous slide)

Note that dplyr made a reasonable guess about which columns to join on (i.e. columns that share the same name). It also told us its choices:

```
## Joining, by = c("year", "tailnum")
```

However, there's an obvious problem here: the variable "year" does not have a consistent meaning across our joining datasets!

• In one it refers to the year of flight, in the other it refers to year of construction.

Luckily, there's an easy way to avoid this problem.

- See if you can figure it out before turning to the next slide.
- Try ?dplyr::join.

left join(

(continued from previous slide)

You just need to be more explicit in your join call by using the by = argument.

• You can also rename any ambiguous columns to avoid confusion.

```
flights.
  planes %>% rename(year built = year), ## Not necessary w/ below line, but helpful
  by = "tailnum" ## Be specific about the joining column
  ) %>%
  select(year, month, day, dep time, arr time, carrier, flight, tailnum, year built, 1
  head(3) ## Just to save vertical space on the slide
## # A tibble: 3 x 11
     year month day dep time arr time carrier flight tailnum year built type
##

## 3
```

Make sure you know what "year.x" and "year.y" are. Again, it pays to be specific.

tidyr

Key tidyr verbs

- 1. pivot_longer: Pivot wide data into long format (i.e. "melt").1
- 2. pivot_wider: Pivot long data into wide format (i.e. "cast").²
- 3. separate: Separate (i.e. split) one column into multiple columns.
- 4. unite: Unite (i.e. combine) multiple columns into one.

¹ Updated version of tidyr::gather.

² Updated version of tidyr::spread.

Key tidyr verbs

- 1. pivot_longer: Pivot wide data into long format (i.e. "melt").1
- 2. pivot_wider: Pivot long data into wide format (i.e. "cast").²
- 3. separate: Separate (i.e. split) one column into multiple columns.
- 4. unite: Unite (i.e. combine) multiple columns into one.

Let's practice these verbs together in class.

• Side question: Which of pivot_longer vs pivot_wider produces "tidy" data?

¹ Updated version of tidyr::gather.

² Updated version of tidyr::spread.

1) tidyr::pivot_longer

```
stocks = data.frame( ## Could use "tibble" instead of "data.frame" if you prefer
  time = as.Date('2009-01-01') + 0:1,
  X = rnorm(2, 0, 1),
  Y = rnorm(2, 0, 2),
  Z = rnorm(2, 0, 4)
stocks
        time
              X Y Z
###
## 1 2009-01-01 -0.2665033 3.8180986 1.942943
## 2 2009-01-02 -0.7235513 0.8787306 -1.684374
stocks %>% pivot longer(-time, names to="stock", values to="price")
## # A tibble: 6 x 3
  time stock price
##
  <date> <chr> <dbl>
##
## 1 2009-01-01 X -0.267
## 2 2009-01-01 Y 3.82
## 3 2009-01-01 Z 1.94
## 4 2009-01-02 X -0.724
## 5 2009-01-02 Y 0.879
                                                                           42 / 54
## 6 2009-01-02 Z
                -1.68
```

1) tidyr::pivot_longer cont.

Let's quickly save the "tidy" (i.e. long) stocks data frame for use on the next slide.

```
## Write out the argument names this time: i.e. "names_to=" and "values_to="
tidy_stocks =
  stocks %>%
  pivot_longer(-time, names_to="stock", values_to="price")
```

2) tidyr::pivot_wider

1 X -0.267 -0.724

1.94 -1.68

3.82 0.879

2 Y

3 Z

2) tidyr::pivot_wider

```
tidy stocks %>% pivot wider(names from=stock, values from=price)
## # A tibble: 2 x 4
   time X Y Z
##
    <date> <dbl> <dbl> <dbl> <dbl>
###
## 1 2009-01-01 -0.267 3.82 1.94
## 2 2009-01-02 -0.724 0.879 -1.68
tidy stocks %>% pivot wider(names from=time, values from=price)
## # A tibble: 3 x 3
## stock 2009-01-01 2009-01-02
  <chr> <dbl> <dbl>
##
## 1 X -0.267 -0.724
## 2 Y 3.82 0.879
## 3 Z
          1.94 -1.68
```

Note that the second example — which has combined different pivoting arguments — has effectively transposed the data.

Aside: Remembering the pivot_* syntax

There's a long-running joke about no-one being able to remember Stata's "reshape" command. (Exhibit A.)

It's easy to see this happening with the pivot_* functions too. However, I find that I never forget the commands as long as I remember the argument order is "names" then "values".

3) tidyr::separate

```
economists = data.frame(name = c("Adam.Smith", "Paul.Samuelson", "Milton.Friedman"))
economists
##
               name
         Adam.Smith
## 2 Paul.Samuelson
## 3 Milton.Friedman
economists %>% separate(name, c("first_name", "last_name"))
    first name last name
##
          Adam
                   Smith
## 1
     Paul Samuelson
## 3 Milton Friedman
```

3) tidyr::separate

```
economists = data.frame(name = c("Adam.Smith", "Paul.Samuelson", "Milton.Friedman"))
economists
###
                name
         Adam. Smith
## 2 Paul.Samuelson
## 3 Milton.Friedman
economists %>% separate(name, c("first name", "last name"))
###
    first name last name
          Adam
## 1
                   Smith
     Paul Samuelson
## 3
     Milton Friedman
```

This command is pretty smart. But to avoid ambiguity, you can also specify the separation character with separate(..., sep=".").

3) tidyr::separate cont.

3 Jill Philanthropist

A related function is separate_rows, for splitting up cells that contain multiple fields or observations (a frustratingly common occurrence with survey data).

```
jobs = data.frame(
  name = c("Jack", "Jill"),
  occupation = c("Homemaker", "Philosopher, Philanthropist, Troublemaker")
iobs
###
                                          occupation
     name
                                          Homemaker
## 1 Jack
## 2 Jill Philosopher, Philanthropist, Troublemaker
## Now split out Jill's various occupations into different rows
jobs %>% separate rows(occupation)
## # A tibble: 4 x 2
###
    name occupation
   <chr> <chr>
###
## 1 Jack Homemaker
## 2 Jill Philosopher
```

4) tidyr::unite

```
gdp = data.frame(
  vr = rep(2016, times = 4),
  mnth = rep(1, times = 4),
  dv = 1:4.
  gdp = rnorm(4, mean = 100, sd = 2)
gdp
## yr mnth dy gdp
## 1 2016 1 1 102.7711
## 2 2016 1 2 100.2260
## 3 2016 1 3 100.9109
## 4 2016 1 4 104.0302
## Combine "yr", "mnth", and "dy" into one "date" column
gdp %>% unite(date, c("yr", "mnth", "dy"), sep = "-")
  date gdp
##
## 1 2016-1-1 102.7711
## 2 2016-1-2 100.2260
## 3 2016-1-3 100.9109
## 4 2016-1-4 104,0302
```

4) tidyr::unite cont.

Note that unite will automatically create a character variable. You can see this better if we convert it to a tibble.

4) tidyr::unite cont.

Note that unite will automatically create a character variable. You can see this better if we convert it to a tibble.

If you want to convert it to something else (e.g. date or numeric) then you will need to modify it using mutate. See the next slide for an example, using the lubridate package's super helpful date conversion functions.

4) tidyr::unite cont.

(continued from previous slide)

Other tidyr goodies

Use crossing to get the full combination of a group of variables.¹

```
crossing(side=c("left", "right"), height=c("top", "bottom"))

## # A tibble: 4 x 2

## side height

## <chr> <chr>
## 1 left bottom

## 2 left top

## 3 right bottom

## 4 right top
```

¹ Base R alternative: expand.grid.

Other tidyr goodies

Use crossing to get the full combination of a group of variables.¹

```
crossing(side=c("left", "right"), height=c("top", "bottom"))

## # A tibble: 4 x 2

## side height

## <chr> <chr>
## 1 left bottom

## 2 left top

## 3 right bottom

## 4 right top
```

See ?expand and ?complete for more specialised functions that allow you to fill in (implicit) missing data or variable combinations in existing data frames.

You'll encounter this during your next assignment.

¹ Base R alternative: expand.grid.

Summary

Key verbs

dplyr

- 1. filter
- 2. arrange
- 3. select
- 4. mutate
- 5. summarize

tidyr

- 1. pivot_longer
- 2. pivot_wider
- 3. separate
- 4. unite

Key verbs

dplyr

- 1. filter
- 2. arrange
- 3. select
- 4. mutate
- 5. summarize

tidyr

- 1. pivot_longer
- 2. pivot_wider
- 3. separate
- 4. unite

Other useful items include: pipes (%>%), grouping (group_by), joining functions (left_join, inner_join, etc.).

Next lecture: Data cleaning and wrangling: (2) data.table
